## ABSTRACT

Recent human effort has been directed at expanding pervasive smart environments. For this, ubiquitous computing technology is introduced to provide all users with any service, anytime, anywhere, with any device, and under any network. However, high cost, long time consumption, extensive effort, and in some cases irrevocability are the main challenges and difficulties for developing ubiquitous systems. Therefore, one solution is to initially simulate, analyze, and validate practices prior to deploying sensing and computational devices in the real world. Simulation, as a performance evaluation technique, has attracted attentions due to its speed, cost-effectiveness, repeatability, scalability, flexibility, and ease of implementation. Moreover, emulation, as a hybrid method, not only offers most simulation advantages but also benefits from tight control of implementation, as well as a certain degree of realistic results. Both simulators and emulators are significant tools for enhancing the understanding of ubiquitous sensor networks (USNs) through testing and analyzing several scenarios prior to actual sensor placements. In this regard, this paper surveys 130 simulation and emulation environments and frameworks, which were originally designed and adapted for USN. Of these 130, the 22 that have been widely used, regularly updated, and well supported by their developers are compared based on multifarious criteria. Finally, several studies that had favorably compared the performance of simulators and/or emulators are examined. We believe the present research findings will be helpful for students and researchers to pick an appropriate simulator/emulator, and for software developers and those who are keen on producing their own environment.

## 1. Introduction

Information technology (IT) has been penetrating into our lives to become highly associated and interwoven with our daily activities. Computers, as user interfaces, enable individuals to connect to the cyber space and facilitate persons-to-persons and persons-to-machines interactions. Due to the rapid advancement and development in IT, cyber space has begun to resemble the real (physical) space more and more (Fig. 1a), because cyber space is becoming a part of our real space (e.g., augmented reality applications). The confluence of cyber space and real space has generated a new space that has been termed *ubiquitous space* (Fig. 1b). In such a smart space, which is a new generation of IT, computers are fragmented and deployed into the environment and computation is made available everywhere and anywhere through *ubiquitous computing* (Weiser, 1993a). The word *ubiquitous* is defined as “existing or being everywhere at the same time” (Agrawal, 1995). The term *ubiquitous computing* (or *ubicom* in

short) was firstly introduced by Weiser (1993b, 1993c), who believed that in the near future humans will not interact with a single computer at a time. Instead, they will encounter invisible networked computers that are embedded in objects and are deployed in the environment. In other words, *ubicom* is seen as a technology by which sensors interact and control the environments in an invisible manner without humans intervention (Keefe and Zucker, 2003). All the elements are connected smartly. Computing fades into the background, rather than dominating the foreground. Ultimately, this *calm* technology will make any service accessible for all users, anytime, anywhere, with any device, and under any network. *Ubicom* technology is becoming pervasive across diverse fields ranging from the military to tourism and medicine to sport.

In computer science, a network is a mixture of communication protocols and link technologies, traffic flows, and routing algorithms (Rahman et al., 2009). Networks can be in wired and wireless forms. Compared with wireless networks, wired networks have been used for several years and can transfer data more safely and securely. However,

**Fig. 1.** Information Technology (IT) spaces: (a) convergence of cyber and real spaces, (b) ubiquitous spaces produced by the confluence of cyber and real spaces.

wires are one of the challenges of such networks. It is arduous to handle interwoven wires and power cords while preserving the network flexibility. Therefore, the developments of wired networks remains challenging due to wiring and rewiring bottlenecks (Patil and Hadalgi, 2012). With the rapid development of wireless technology, wireless networks are becoming widespread. Compared with traditional wireless networks, wireless sensor networks (WSNs) have more throughputs and productivity (Egea-Lopez, 2005; Ge, 2016).

The development of a ubiquitous system necessitates an infrastructure capable of supporting interrelated processing devices. Specifically, this infrastructure must be able to handle tens to thousands of static and mobile devices (known as sensor nodes or motes) where communication is performed by means of wireless transmission. Sensor nodes, with respect to their capability, are responsible for monitoring and collecting parameters (Kiess and Mauve, 2007), then processing the data locally or transmitting the data to one or more routers at ultra-high speed through ubiquitous sensor networks (USNs) (Dwivedi et al., 2010; Shen and Bai, 2016). These nodes are physically tiny, normally cheap, and operationally low-power devices built around a microcontroller and equipped with one or more sensors, memory, radio-frequency transceiver, and a power source (Jevtić et al., 2009; Curiać, 2016). They are deployed either stationary or movable but work unobtrusively (Rashid and Rehmani, 2016).

WSN and USN differ noticeably. In WSN, sensors are spatially distributed and responsible for monitoring environmental conditions (e.g., temperature, noise, and motion), then transferring these data to central stations in wireless manner. USNs are the convergence of advanced invisible electronic devices, the Internet, and wireless networks, which not only inherit WSN features but also impose smartness into the system (e.g., the temperature separately adjusts based on individuals' contexts). Hence, WSN can be considered an infrastructure of ubiquitous computing (Kim and Kim, 2012). Although USN has a broader scope, both WSN and USN may have their own meaning in different countries and applications. In this paper, these terms convey the same meaning and may be used interchangeably.

USN is the core of an ubicomp system. To have reliable, secure, and durable USN communications, a large variety of protocols is introduced in order to make use of the resources efficiently, routing the sensor packets accurately, and preserving the wireless communications effectively (Akyildiz, 2002; Yick et al., 2008). Also, while designing USN communications, the following factors should be considered: topology of system (i.e., the arrangement of the various elements (nodes, links, etc.) of a computer network), energy consumption effects, scheduling strategies (i.e., work specified by some means is assigned to resources that complete the work), fault tolerance (i.e., continue working to a level of satisfaction in the presence of faults), data synchronization (i.e., keeping multiple copies of a dataset in coherence with one another), process synchronization (i.e., multiple processes are to join up at a certain point, in order to reach an agreement or commit to a certain sequence of action), communication range (i.e., the distance by which nodes can transfer data effectively), and coordination protocols (Leelavathi, 2013). Furthermore, given the constraints in sensor networks, such as limited resources (i.e., memory, power, quality of service, and processing ability), decentralized communications (i.e., allocation of resources, both hardware and software, to each individual

node), multi-tasking (i.e., simultaneous execution of multiple applications), fault tolerance results (Leelavathi, 2013), re-programmability, and security, the correlation of algorithms and protocols for these networks initially needs to be tested and evaluated. Therefore, saving time, cost, and effort requires the development of practices to be initially simulated, analyzed, and validated prior to deploying sensing and computational devices in the real world.

In this context, this research *aims to* introduce and compare the available simulators and emulators environments and frameworks for USN applications. The rest of this paper is organized as follows. In Section 2, we discuss the performance evaluation techniques related to USN, as well as their corresponding merits and demerits. Section 3 describes and compares the USN operating systems (OSs). Related studies in reviewing USN simulation and emulation environments are comprehensively presented in Section 4. In Section 5, an overview and classification of 130 USN simulators' and emulators' environments and frameworks are provided. Section 6 compares several USN simulators and emulators based on multifarious criteria and follows with pros and cons of the selected ones in tabular format. In Section 7, performance results and conclusions of applying simulators and emulators from previous studies are addressed. Potential future works and open issues related to USN simulation and/or emulation are discussed in Section 8. Finally, we summarize and conclude with final remarks in Section 9. All the acronyms and abbreviations used in this paper along with their definitions are provided in Table 1.

## 2. USN performance evaluation techniques

Several techniques have been introduced for performance evaluation of protocols and algorithms in USN, including analytical modeling, simulation, emulation, testbed, and real-world experimentation (Imran et al., 2010). Analytical models are a set of equations that represent the performance of a system. Although analytical models simplify the modeling procedure, they cannot accurately represent the inherent complexity of sensor networks (Krop, 2007). Simulation has been cited as the most frequent and effective method for designing and developing network protocols and algorithms (Imran et al., 2010). By using simulators various scenarios of the real environment can be modeled. Also, they provide the possibility of testing and debugging protocols at any stage of design. Emulation, as a hybrid method, is a combination of hardware and software components accompanying simulation possibilities for network modeling (Kiess and Mauve, 2007). Emulators use

firmware as well as hardware to execute simulations in laboratory conditions. Since emulators can be utilized in real environments, they potentially perform precisely in comparison to simulators (Patil and Hadalgi, 2012). Physical testbeds are frameworks for real implementation of protocols and algorithms. Testbeds not only allow remote configuration, running, and monitoring experiments but also support model, protocol, and algorithm evaluation. They have bridged the gap between simulation and deployment of real devices (Kiess and Mauve, 2007). A comprehensive survey of current testbeds can be found in Farooq and Kunz (2014), Chawda and Dwivedi (2014), Steyn and Hancke (2011), Kim (2015), El-Darymli and Ahmed (2012), Horneber and Hergenroder (2014). Real-world experimentation allows feasible and actual sensor deployment practices. All the functions are set in the reality and no incorrect or inaccurate presumption is made. This is the ultimate stage of the validation of protocols and algorithms (Patil and Hadalgi, 2012). Each of the aforementioned techniques has its own pros and cons, which are summarized in Table 2.

USN performance evaluation techniques range from purely software-based to solely hardware-based techniques. To clarify the nature of these techniques, Fig. 2 depicts the contribution of each in terms of the proportion of virtual and real spaces which they use. In this regard, analytical models and simulators only perform in virtual space, and no

physical deployment is implemented in real space. For emulators and testbeds this sounds different. These techniques apportion their throughput to cyber and real spaces. In the former, cyber space has a much great portion, while in the latter the majority of the implementation is dedicated to real space. Real deployment, as the latest evaluation technique, fully concentrates on real space. All the implementation and manipulation in this technique go through physical deployment (Halder and Ghosal, 2016). Considering all the positive and negative aspects of USN performance evaluation techniques, this research aims to investigate simulation and emulation concepts and environments. This will not only enable us to assess the nature, ability, and productivity of USN simulators and emulators but also allows evaluating techniques that are performed purely in cyber space and those in a mixture of cyber and real spaces.

The difference between agent-based modeling and ubiquitous computing can be contentious. On the one hand, agent-based models (ABMs) have been used diversely to study the complex interaction of entities of the real world (Chen et al., 2008). Analytical models and simulators are the prominent performance evaluation techniques used by ABMs. In other words, ABMs are summarized in algorithms within simulators through virtual space. By achieving a certain degree of confidence from agent-based modeling, physical practices may be implemented into real space.

**Fig. 2.** The proportion of performance evaluation techniques from cyber space (CS) to real space (RS).

Fig. 3. From agent-based modeling to ubiquitous computing.

ABMs, however, suffer from the deficiencies of analytical models and simulators such as over simplification and high level of abstraction, to name a few. On the other hand, ubiquitous computing takes place everywhere and is not limited to boundaries. In contrast to ABMs, ubiquitous computing is accomplished by real deployment of pervasive computing devices in real space. However, agent-based modeling can be a prerequisite step for ubiquitous computing. To clarify these terms, Fig. 3 demonstrates the stage of ABM and ubiquitous computing by means of performance evaluation techniques.

There is a tradeoff between ABM and simulators. By ABM, a set of rules is defined at agent level and their interaction is modeled explicitly. Simulators, as experimental tools, typically convey a general meaning and cover broader domain. They are more or less dependent on the predefined rules in the software. However, the rules at ABM can be imported to simulators in order to determine the behavior of the whole system at a global level. This procedure is known as multi-agent simulation (Wooldridge, 2009). Nevertheless, simulators cannot handle agents and their corresponding rules.

## 2.1. Simulation

The imitation of the real-world's conditions and processes in the course of time is known as *simulation*. By simulation, the system behavior can be characterized and analyzed, what-if questions can be raised, and systems with close similarity to real conditions can be designed. Significant information regarding the feasibility, productivity, and efficiency of a system can be assessed by simulation prior to real deployment of actual implementation (Banks, 1998). Normally, to carry out a simulation, a model needs to be developed. Such a model demonstrates the main properties, characteristics, and treatment of the desired system/process. The model represents the system itself, whilst the operation of the system in the course of time is shown by simulation. However, it is not trivial to derive a trustworthy conclusion from a simulation result (Mishra, 2012). Diverse steps exist during a simulation and may vary with respect to the purpose of simulation. These steps are not necessarily sequential and can be applied in non-consecutive manner. Nevertheless, evaluating the performance of the model requires cyclic revision and thorough evaluation of the functionality of the simulation. Fig. 4 outlines the simulation process and steps as they are concisely described in Madani et al. (2010).

Fig. 4. Phases in simulation studying (extending the textual descriptions of Madani et al. (2010)).

### 2.1.1. Simulation types

Three types of simulation have been mentioned in computer science literature: *Monte Carlo simulation*, *Trace-driven simulation*, and *Discrete-event simulation*. Monte Carlo simulation is a static simulation or one without a time axis. It is used for modeling probabilistic events whose characteristics do not vary over time. Also, Monte Carlo simulation is utilized to appraise non-probabilistic expressions by making use of probabilistic approaches. Trace-driven simulation uses a trace as an input in the process of simulation. A trace is defined as a time-ordered history of phenomena in a real system. In general, Trace-driven simulation is used in analyzing or tuning resource management algorithms. Discrete-event simulation, in contrast to continuous-event simulation, uses a discrete-state model of the system for simulation and is used due to the variable system state which is described by the number of jobs at various devices. Time in discrete-event simulation can be discrete or continuous (Jain, 2008). The last two simulation types are widely used in USN due to their high performance and scalability (i.e., possible number of static and mobile sensors).

### 2.1.2. Simulation execution

Simulators either run via *synchronous* or *asynchronous* modes. *Synchronous simulation* (Peacock et al., 1979), on the one hand, is the simplest simulation method and is a round-based technique: Firstly, the global time increases by one unit via the framework. Secondly, the nodes move with respect to their mobility models and the connections are updated according to the connectivity model. Finally, this procedure iterates over nodes (ETH, 2008). Synchronous simulation has positive aspects, including ease of implementation, performance predictability, and low overhead (Xu and Chung, 2004). However, it tends to suffer from weak load balancing and communication costs due to the synchronization steps between rounds. In brief, synchronous simulation is appropriate for simulations with short computational granularities and great round parallelism (Shu, 2011). On the other hand, *asynchronous simulation* is highly based on events. A number of message and timer events are aligned in time intervals which should take place in order. The events are picked and executed via the framework repeatedly (ETH, 2008). Conservative simulation and optimistic simulation are two types of asynchronous simulation. Comparing these two simulation modes, synchronous simulation runs slower than asynchronous simulation mainly because synchronous simulation meets all the nodes including the ones that are nonfunctional. This condition is not applied for asynchronous simulation. In this mode, only the messages and timer events are processed and unnecessary rounds are not implemented. Asynchronous simulation mode does not support node movement because the continuity of nodes mobility cannot be characterized as events (ETH, 2008).

### 2.1.3. USN simulation

In the USN domain, simulation is one of the most prevailing appraisal procedures for the progression of wireless network protocols and communication frameworks, and for assessing the available ones in different scenarios (Singh et al., 2008). The simulators designed for USN purposes are commonly designed to consider the development constraints (e.g., node and communication). Based on the nature of constraints, simulation tools are classified into (1)

oriented network, and (2) oriented node classes (Diallo, 2014). Oriented networks concentrate on the wireless networks behavior and the protocol stack of the operation. These simulators are initially designed for network simulation and then extended for USN purposes. Examples of this class of simulator are OMNet++, NS-2, and J-Sim. Oriented node, as the second class of simulators, concentrates on the functionality of a single node that contains simple communication models. These simulators are particular to targeted nodes and their OSs. Furthermore, these simulation tools are able to determine the compatibility of a node with an application. Examples of this class of simulator are TOSSIM, ATEMU, and SENS. Two common aspects are considered by these two classes: (1) the correctness of the simulation models, and (2) the suitability of a particular tool to implement the model. Generally, a USN simulator contains multiple modules, including (Carley, 2005):

- *Node* is a device composed of both hardware and software in USN. Nodes components are actuator, sensor, processor, transceiver, network protocol, energy resource, and application.
- *Event* represents substantial functionalities including the time in which an event takes place.
- *Medium* module enables nodes to transmit signals and informs the nodes regarding affective signals.
- *Environment* module enables the propagation of physical phenomena, such as humidity, sound, temperature, and light to be modeled.
- *Transceiver* hardware determines the state of each sensor node (i.e., sleep, standby, receive, and transmit) as well as nodes power consumption.
- *Physical Protocol* is known as the lowest layer of a network stack. It enables services such as transceivers state alteration and packet transmitting and receiving.
- *MAC Protocol* resides above the physical protocol. It is normally installed on the node processor software. MAC protocol enables services such as alteration of MAC layer state and defining protocol parameters.
- *Routing Protocol* is located above the MAC protocol. It enables messages to be routed between network hobs.
- *Application Layer* lies on the top of the network stack. It implements an USN application through connecting with lower layers, sensors, and actuators.

#### 2.1.4. USN simulator categories

Simulation can be applied at various abstraction levels, from generic simulation, where only the most important features are modeled, to highly detailed simulations, where particular aspects are represented. A research contribution (Eriksson, 2009) has categorized the simulators based on the level of abstraction.

- *Generic Network Simulators* concentrate on network simulation more than node simulation. High level languages are used for writing simulation applications, which is far removed from real sensor language. Also, the same programming language is used for applications and protocol codes. Most of the network simulators provide simulation of network stack, MAC protocol, and radio medium. Generic network simulators are effective for assessing new communication protocols. However, they are less operational for interoperability evaluation or exploring software bugs.
- *Code Level Simulators* make use of similar codes as are utilized in actual sensor network nodes. So, they enable network stacks executions which are presented for a particular OS. Code level simulators not only enable the simulation of radio medium but also provide sensor simulation. They are effective in the detection of software bugs (e.g., deployable code or logical error), but they are not appropriate for hardware ones (e.g., CPU architecture or timing).
- *Firmware Level Simulators* consider both sensor node emulation

and firmware that run in the actual sensor network. Firmware level simulators enable detailed simulation and produce accurate implementation results. Furthermore, they facilitate radio medium simulation in addition to microprocessor and radio chip emulation. Because of detail simulation, firmware level simulators execution times are higher than those of generic network or code level simulators.

Another study (Shu, 2011) has classified the simulators into three major categories based on the level of complexity.

- *Algorithm Level Simulators* consider the logic, data structure, and presentation of algorithms. Algorithm level simulators concentrate on graph data structure to represent nodes connections rather than detailed communication modeling. They enable large network simulation but with no simple MAC layer protocol.
- *Packet Level Simulators* execute the physical layer and data link into the network stack. Thus, they provide MAC protocols and radio models to be implemented, which are the ones that are feasible for propagation, collision, fading, and noise and wave diffraction.
- *Instruction Level Simulators*, also named emulators, provide CPU execution modeling at the level of instructions.

#### 2.1.5. Requirements for USN simulation

Given the multifarious features of USN in decentralized communication, such as multitasking, heterogeneity, numerous sensor nodes, and limited resources, the design and development of a simulator is a challenging issue (Du, 2010). In this context, six key factors for USN simulation tools should be taken into consideration.

- *Fidelity* focuses on the faithfulness of simulation as well as prediction of system behavior. In this regard, for radio channels, physical environment, node system, and accurate models need to be developed.
- *Scalability* represents the supported number and density of sensor nodes by a USN simulator. As USN applications require the deployment of many sensor nodes, higher scalability of a simulator is an advantage.
- *Energy aware* is a critical feature in USN simulators. Since sensor nodes have restricted resources of energy (i.e., battery or solar cells), power consumption and timing information need to be modeled accurately via simulators prior to the real deployment of sensor nodes.
- *Extensibility* enables users to modify the available modules or import new ones to the simulator. A user-friendly interface with high modularity aids users to add or alter the functionalities.
- *Heterogeneity support* enables the integration of a variety of multifarious elements in USN simulation tools. This includes modeling of various nodes and their interconnections.
- *Graphical User Interface (GUI)* facilitates the implementation of the network topology and the composition of modules. It can also speed up debugging, tracing, and visualization of the simulation results.

#### 2.1.6. Simulation criteria assessment

There are multifarious criteria for assessing a simulator. Key properties such as reusability and availability, performance and scalability, support for rich-semantics scripting languages to define experiments and process results, and graphical, debugging, and trace support should be present in a good simulator (Egea-Lopez, 2005). Also, there are diverse critical features for simulators which are categorized into input, processing, output, support, and cost groups (Banks, 1991). Each category comprises several criteria that are outlined and extended in Table 3. Based on the design goals, architecture, and applications abstraction level, a combination of these features can be present in a simulator.

**Table 3**  
Features of simulation software.

Input features	Processing features	Output features	Environment features	Cost features
<ul style="list-style-type: none"> <li>Interface to other software</li> <li>Input data analysis capability</li> <li>Portability</li> <li>Syntax</li> <li>Input flexibility</li> <li>Modeling flexibility</li> <li>Modeling conciseness</li> </ul>	<ul style="list-style-type: none"> <li>Execution speed</li> <li>Model size</li> <li>Material handling</li> <li>Random variant generators</li> <li>Reset</li> <li>Independent replications</li> <li>Attributes</li> <li>Global variables</li> <li>Programming</li> <li>Conditional routing</li> <li>Rare event simulation</li> </ul>	<ul style="list-style-type: none"> <li>Standardized reports</li> <li>Customized reports</li> <li>Confidence intervals</li> <li>Business graphics</li> <li>File creation</li> <li>Tracing capability</li> <li>Data base maintenance</li> <li>Post processing and statistical analysis</li> </ul>	<ul style="list-style-type: none"> <li>Ease of use</li> <li>Ease of learning</li> <li>Quality of documentation</li> <li>Animation capability</li> <li>Ease of development</li> <li>Quality of picture</li> <li>Smoothness of movement</li> <li>Portability for remote viewing</li> <li>CAD interface</li> <li>On-line help</li> <li>On-line tutorial</li> <li>Customer support</li> <li>Training</li> <li>Technical support</li> <li>Update and enhancement</li> </ul>	<ul style="list-style-type: none"> <li>Hardware requirement</li> <li>Time spent learning to use the software</li> <li>Time required for building models</li> </ul>

## 2.2. Emulation

The tools which comprise of software and hardware to perform the simulation are typically known as *emulators*. In an emulator, the actual hardware (e.g., motes), beside simulated components (e.g., links and traffic), aims to provide realistic performance for USN applications. The emulator usually has high scalability for simultaneously emulating several sensor nodes. Comparing to simulators, emulators are implemented in real sensor nodes and run real application codes, which improves their performance precision. Emulators are appropriate for timing interactions among sensor nodes as well as for fine tuning network level and sensor algorithms (Leelavathi, 2013).

In a research contribution (Kiess and Mauve, 2007), emulators are categorized into *physical layer* and *MAC layer* classes. For physical layer emulators, a real system is comprised of all the network layers except the physical layer. These emulators rip the emitted radio signals via nodes wireless interfaces in order to experience the effects that radio waves may face in reality. On the contrary, inverse physical layer emulators act the other way round, i.e., the overhead parts of the network group are simulated and packets using real hardware are transmitted. For the MAC layer emulator, a real system is comprised of all the network layers except the physical layer and the MAC layer.

### 2.2.1. Taxonomy for USN simulation and emulation tools

Importing node models into network simulators has been an evaluation approach of USN simulators. Two types of node model have been introduced as (1) *simulators node models*, and (2) *node emulators*. The latter relates to instruction level simulators of the nodes microcontrollers, and is comprised of sensors and transceivers extensions as well as diverse peripheral models. *Node emulators* enable modeling of the network and inserting node models into network simulators (Du, 2010). In this regard, USN evaluation is categorized into the following four classes.

- *Network simulators with node models* focus on discrete-event timing, radio medium, network modeling, and more or less the sensor node sleep duty cycles.
- *Network simulators with node emulators* benefit from the merits of both the network simulators and node emulators. A detailed network model can be achieved through network simulators. Also, accurate timing information of the tools can be gained by the node emulator.
- *Node system simulator with network models* operates frequently at the system level via hardware description languages, such as SystemC. Such languages enable node hardware modeling in diverse abstraction levels with various details, such a system level, transaction level, and register transfer level.

- *Node emulators with network models* can execute the application code directly. The node emulators can be classified as (1) instruction set simulators for special microcontrollers, and (2) emulators designed to emulate the execution of the application code of an OS.

### 2.2.2. Simulation and emulation output

Simulation and emulation outcomes can be represented as graphs, text files, and animations of a trace file. Graphs facilitate comparison among multiple protocols. Graphs can demonstrate the variation in packet delivery amount, network delay and throughput, and several other parameters for network performance assessment. The output text files can be inputs for other simulators or programs. Ultimately, every event that happens in the simulation process can be recorded via a trace file (Christhu raj, 2013).

## 3. USN operating systems

As stated before, USN is comprised of several tiny sensor nodes that communicate through wireless networks. The components of sensor nodes hardware such as physical sensor, microprocessor/microcontroller, memory, radio transceiver, and battery need to be operated in orderly and controlled manner. This process is conducted via an OS. Thus, each sensor node requires an OS for controlling the hardware, providing hardware abstraction to application software, and reducing the gap between applications and the underlying hardware (Sohraby et al., 2007). In other words, OS acts as a resource manager for allocating resources correctly and effectively without any conflict (Farooq and Kunz, 2011). For USN purposes, OSs must provide basic functionalities, efficient power management mechanisms, field reprogramming mechanisms, and a configurable communication stack, as well as the ability to abstract heterogeneous sensing hardware in a uniform fashion and operate with limited resources (Fröhlich and Wanner, 2008).

Phani et al. (2007) presented a classification framework for USN OSs based on their important features, i.e., architecture, execution model, reprogramming, scheduling, and power management. In addition, it proposed adequate OSs for various classes of USN applications. Dwivedi et al. (2009) reviewed the architecture and performance analysis of five USN OSs: TinyOS, Contiki, Mantis OS, SOS, and Microsoft.NET Micro. Dong (2010) addressed the major challenges in designing OSs and reviewed some important features of TinyOS, Contiki, Mantis OS, SOS, Nano-RK, RETOS, and LiteOS OSs. Over the past years, a variety of OSs has been introduced to facilitate developing USN applications. A list of the identified ones is presented in alphabetical order in Fig. 5. Reviewing all of them is beyond the scope of this research, but for further information please refer to Phani et al. (2007). Aside from the mentioned OSs, several studies have tried to

- AmbiCompVM	- Embedded Linux	- LiteOS	- NanoVM	- SenSpire OS
- AVR3	- EMERALDS	- µCOS	- OSPM	- SensorOS
- Bertha	- EYES	- MagnetOS	- OSSTAR	- SmartOS
- BTnutOS or NutOS	- FreeRTOS	- Mantis OS	- ParticleVM	- Squawk VM
- Contiki	- GenOS	- Maté	- PeerOS	- SOS
- CORMOS	- Jallad	- Microsoft .NET Micro	- PicOS	- T2
- CustomOS	- kOS	- MoteWorks	- Pixie OS	- TinyOS
- CVM	- KVM	- Nano-QPlus	- RETOS	- YATOS
- DCOS	- LORIE	- NanoRK	- SenOS	- VMSTAR

Fig. 5. List of sensor network OSs.

enhance OSs capabilities in diverse dimensions, for instance, improving OS reliability (e.g., t-kernel, Harbor, and Neutron), enabling real-time support (e.g., FIT), extending the programming model (e.g., protothreads and TOSThreads), and enabling reprogramming support (e.g., Deluge, FlexCup, Stream, and Elon) (Dong, 2011).

#### 4. Related works

Over the last decade or so, a plethora of researches has exploited USN simulators and emulators, demonstrating the utility and significance of these tools in USN applications. Consequently, a considerable body of researches has *specifically* and *generally* overviewed, compared, and evaluated different aspects of the USN simulation and emulation environments/frameworks.

From the specific point of view, Merrett (2009) investigated the energy-aware suitability of a number of USN simulators, and subsequently proposed a novel structure for simulating energy-aware USNs. Zhu (2012) introduced and assessed the coverage and connectivity features of popular USN simulation tools. Mekni and Moulin (2008) provided background on a number of different sensor web simulation tools along with the advantages and the drawbacks of each. Accordingly, they proposed an evaluation methodology in order to assess the capabilities of each simulation tool. Although the significance of such specialized investigations is indubitable, the outcomes cannot be extended to all the features of that distinguished tool. In other words, USN applications are normally comprised of a set of stages and implementations which a simulator/emulator should be able to handle. The strength of a simulator/emulator in specific feature does not guarantee that other features perform well too. Therefore, several general aspects of simulators/emulators require to be evaluated in parallel.

From the general standpoint, the majority of published survey papers have investigated USN simulation and emulation environments/frameworks either in *quantitative* or *qualitative* manners, and rarely a combination of these two can be seen in literature. By the quantitative studies, the majority of researches have reviewed a large number of simulators and/or emulators at naive levels by providing short descriptions and general overviews of the tools so far. For example, Dwivedi and Vyas (2011) glimpsed 63 simulators, 14 emulators, 19 data visualization tools, 46 testbeds, 26 debugging tools, 10 code-updating tools, and 8 network monitors in USN. Musznicki and Zwierzykowski (2012) presented the state-of-the-art, main features, and the GUI snapshots of the 35 widely used USN simulation and emulation environments. Dwivedi and Vyas (2014) listed 74 USN simulators and emulators accompanying their features and properties. Although such studies are treated as overview articles, none of them compared and evaluated simulation and/or emulation tools in depth.

By the qualitative studies, a few research contributions have studied a limited number of simulators and/or emulators by providing meticulous details and specific features of those tools. For example, Karl (2005) deeply compared the NS-2 simulator and the TOSSIM emulator in terms of models, visualization tool, architecture, event scheduler, and components. Khan (2011) evaluated the interface, accessibility and user support, availability of USNs modules, extensibility, and scalability of seven (i.e., NS-2, OMNeT++, GloMoSim, OPNET, SENSE, TOSSIM, GTSNetS) simulation and emulation environments.

Stetsko et al. (2011) effort was toward examining the antenna setting, radio propagation, noise, medium access control, topology, and energy consumption modeling just in four (i.e., Castalia, MiXiM, TOSSIM, WSNNet) USN simulators and emulators. It is evident from the studies alike the ones abovementioned that particular features of limited number of tools have been normally assessed and there is no necessity that two studies evaluate identical features of one simulator/emulator. For example, both Karl (2005) and Khan (2011) studied NS-2, albeit with different criteria. Khan (2011) and Stetsko et al. (2011) studied TOSSIM with almost distinct properties.

Table 4 presents a chronological overview of both quantitative and qualitative studies over the past decade. This summary is conducted by reviewing the publicly available and published documents including journal articles, book chapters, conference proceedings, theses, and technical reports. Among the preceding contributions related to the evaluation of simulators and emulators for USN, none of them have profoundly focused on all the present developed/extended tools so far, very few of them (e.g., Nayyar and Singh, 2015) have comprehensively evaluated the prominent tools based on various criteria, and no structured classification has been suggested for these tools in the literature. Moreover, to the best of our knowledge, there is no research contribution that has studied the performance assessment parameters of simulators and emulators in USN scenarios. Furthermore, a few new tools have recently released and some of the well-known traditional simulators/emulators have been developed since past few years that should be examined. Therefore, there is an overriding need to fill these gaps in a new survey article.

This survey is different from the existing reviews in three salient aspects. Firstly, this survey expands its investigation to all of the (founded) USN simulation and emulation environments/frameworks along with their derivatives and extensions produced so far. Specifically, this article is not only focusing on the quantitative aspect of simulation and emulation environments (i.e., 130 tools) but also is qualitatively assessing the ones which have been widely used, regularly updated, and well supported by their developers based on multifarious criteria. It also suggests a categorization for these tools on general- and specific-purpose basis. Secondly, this survey provides a general picture on the state-of-the-art evaluation criteria for both simulators and emulators. This consequently determines which prominent tool is adequate for what kind of purpose (i.e., academic, research, or commercial). Thirdly, this survey proposes a number of performance assessment parameters for simulators and emulators in ubiquitous simulation and emulation scenarios.

#### 5. Overview of USN simulators and emulators

Numerous tools have been developed for simulating and emulating USN. They vary in terms of architecture, features and characteristics, modeling methodology, and performance (ZVKOVIC, 2014). Utilizing or developing a simulator/emulator necessitates becoming familiar with the available tools, evaluating their pros and cons, and choosing the appropriate one for the application. This section, therefore, introduces 130 USN simulation and emulation environments and frameworks, as well as their derivatives, which were *originally designed* and *adapted* for USN. The USN simulators and emulators provided in the following are the ones that we found in the literature at

**Table 4**

Contribution of the reviewed literature in USN simulators and emulators.

Reference	Year	Simulators and/or Emulators	Description
(Khemapech et al., 2005)	2005	NS-2, SENSE, GloMoSim, SENS, SensorSim, ATEMU, OMNeT++, Prowler, J-Sim, Shawn, TOSSIM, OPNET, TOSSF	Properties
(Egea-Lopez, 2005)	2005	NS-2, OMNeT++, J-Sim, NCTUns2.0, JiST/SWANS, GloMoSim, SSFNet, Ptolemy II, TOSSIM, EmStar/EmSim/EmTOS, SENS, ATEMU, Prowler/JProWler, SNAP	Overview and implementation issues
(Karl, 2005)	2005	NS-2, TOSSIM	Models, visualization, architecture, components
(Egea-Lopez, 2006)	2006	SSF, SWANS, J-Sim, NCTUns2.0, NS-2, OMNeT++, Ptolemy, SNAP, ATEMU, EmStar, TOSSIM	Models, type of visualization
(Neves et al., 2007)	2007	NS-2, J-Sim, SENSE	USN application in medicine, overview, and comparison
(Mekni and Moulin, 2008)	2008	NS-2, OPNET, OMNeT++, J-Sim, NCTUns, JiST/SWANS, GloMoSim, SSFNet, TOSSIM, TOSSF, TYTHON, EmStar/EmSim/EmTOS, ATEMU, SENSE, SENS, Prowler/JProWler, ModelNet/Nisnet, SwarmNet/Shawn, Glonemo, Aurora	Evaluation in terms of reusability and extensibility, performance and scalability, operating system portability, semantics scripting languages, realism level of virtual environment, graphics, and debug and trace
(Singh et al., 2008)	2008	NS-2, GloMoSim, OPNET, SensorSim, J-Sim, SENSE, OMNeT++, Sidh, SENS, TOSSIM, ATEMU	Overview
(Köksal, 2008)	2008	J-Sim, OMNeT++, NS-2, OPNET	Comprehensive overview, features, and comparison

(Sethi et al., 2012)	2013	NS-2, TOSSIM, GloMoSim, UWSim, J-Sim, SENS, COOJA, SENSE, VisualSense, JProwler, Shawn, Castalia	Comparison table
(Chandrasekaran et al., 2013)	2013	NS-2, TOSSIM, GloMoSim, QualNet, OPNET, J-Sim, OMNeT++	Overview, architecture, merits and limitations, and comparison table
(Khalifa, 2013)	2013	NS-2, NS-3, OMNeT++, Wireshark (Ethereal), OPNET, GloMoSim/QualNet, J-Sim, GNS3	Comparison table
(Bhatt and Kathiriyi, 2013)	2013	J-Sim, OMNeT++, NS-2, OPNET	Overview, GUI, comparison table of simulation features
(ZVKOVIC, 2014)	2014	NS-2, NS-3, GNS3, Wireshark (Ethereal), OPNET, OMNeT++, GloMoSim/QualNet, J-Sim, JiST/SWANS, VisualSense, Ptolemy II, TOSSIM, Castalia, EmStar, ATEMU, SENSE, SENS, JProwler, Avrora, COOJA, Shawn	Overview, comparison tables, advantages and disadvantages
(Sahin and Ammari, 2014)	2014	NS-2, OMNeT++, J-Sim, OPNET, TOSSIM	Comprehensive overview, features, components, comparison tables, and shortcomings
(Dhviya and Arthi, 2014)	2014	NS-2, EmStar, GloMoSim, Shawn, UWSim, VisualSense, J-Sim, OMNeT++, Aqua-Sim, QualNet	Underwater USN overview, merits and demerits, and comparison table
(Dwivedi and Vyas, 2014)	2014	Simulators: Network Simulator (NS-2 and NS-3), Mannasim, TOSSIM, TOSSF, PowerTOSSIM Z, ATEMU, COOJA, GloMoSim, QualNet, SENSE, VisualSense, AlgoSenSim, GTNetS, OMNeT++, Castalia, J-Sim, JiST/SWANS, JiST/SWANS++, Avrora, Sidh, Prowler, JProwler, LecsSim, OPNET, SENS, EmStar, EmTOS, SenQ, H-MAS, SensorSim, Shawn, NetTopo, Atarraya, SSFNet, WiseNet, SimGate, SimSync, SNetSim, SensorMaker, TRMSim-WSN, PAWiS, OLIMPO, DiSenS, WISDOM, Sinalgo, Sensoria, Capricorn, SIDnet-SWANS, Starsim, SNSim, SNIPER-WSNim, SNAP, SimPy, Mule, CaVi, Ptolemy, Maple, WISENES, WSN-Worldsens and WSim, LSU Sensor Simulator, WSNge, TikTak, Motesim, Boris, SmartSim, WSNim, EnergySim, MOB-YOSSIM, AEON, Sensor Security Simulator (S3), Wireless Sensor Network Localization Simulator, Xen WSN Simulator, UWSim, Network in a box (NAB)	Overview, categorization of USN-specific simulators
(Roy and Jain, 2015)	2015	QualNet, NS-2, NS-3, OPNET modeler, Net Sim, OMNeT++, J-Sim	Overview
(Nayyar and Singh, 2015)	2015	NS-2, NS-3, OMNeT++, J-Sim, Mannasim, SensorSim, NRL SensorSim, NCTUns, SSFNet, GloMoSim, QualNet, sQualNet, OPNET, SENSE, DRMSim, NetSim, UWSim, VisualSense, Viptos, Ptolemy II, SENS, Shawn, SIDnet-SWANS, SIDH, NetTopo, WSim/Worldsens/WSNet, WSN Localization Simulator, Prowler, MATLAB, PiccSIM, LabVIEW	Overview, architecture, interface/GUI, and comparison table
(Minakov, 2016)	2016	NS-2, NS-3, Castalia, MiXiM, PAWiS, WSN, DANSE, NetTopo, PASES, Sense, TOSSIM, Avrora, COOJA/MSPSim, VIPTOS	Overview, categorization of simulators, comparative study
(Fahmy, 2016)	2016	NS-2, NS-3, GloMoSim, OPNET, OMNeT++, TOSSIM, ATEMU, Avrora, EmStar, SensorSim, NRL SensorSim, J-Sim, Prowler/JProwler, SENS, SENSE, Shawn, SenSim, PAWiS, MSPsim, Castalia, MiXiM, NesCT, SUNSHINE	Overview, component, structure

the time of this writing. The literature review for tool selection was based on the online publications (i.e., original and survey articles, book chapters, conference proceedings, thesis, and technical reports) as well as the tool developers' websites and tutorials. Specifically, these tools are divided into simulators and emulators. Then, simulators are classified into general-purpose and specific-purpose classes (see Fig. 6). General-purpose tools are those that already existed before

the emergence the USN concept. The functionality of the simulator/emulator was then extended and adapted for USN purpose. In contrast, specific-purpose class tools are the new simulating/emulating tools that have been created solely for USN purpose. Of these 130 simulators and emulators, the 22 that have been widely used, regularly updated, and well supported by their developers are compared based on multifarious criteria.

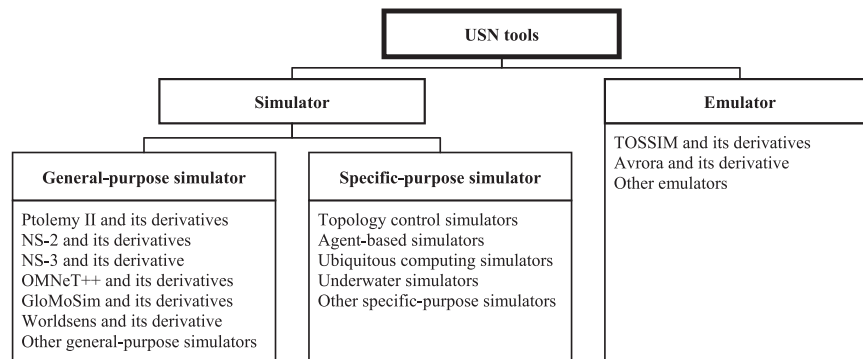

Fig. 6. Classification of simulation and emulation environments/frameworks.

### 5.1. USN simulation environments

This sub-section concisely introduces 41 general-purpose USN simulators and their derivatives as well as 66 specific-purpose ones. Meanwhile, the corresponding designer/developer, the latest version, and the software link (if any) are provided for general- and specific-purpose simulation tools in Tables 5 and 6, respectively.

#### 5.1.1. General-purpose simulators

##### • Ptolemy II and its derivatives

1. **Ptolemy II** is a set of Java packages which support various models of simulation, including continuous time, dataflow, and discrete-event. They are an actor-oriented and component-based design of J-Sim (described later as tool no. 33) (Ptolemy, 2017).
2. **Viptos** (Visual interface between Ptolemy and TinyOS) is a graphical development and simulation environment for TinyOS-based (a component-based, event-driven runtime environment) USN. It is built on Ptolemy II and TOSSIM—an interrupt-level discrete-event simulator for homogeneous TinyOS networks (Cheong et al., 2005; Viptos, 2017).
3. **VisualSense** is a visual model for ubiquitous and sensor network systems. It was built on Ptolemy II, and preserves the semantics of discrete event, although explicit wires are not required because of changing the mechanism of connecting components (Baldwin, 2005; VisualSense, 2017).

##### • NS-2 and its derivatives

4. **NS-2** (Network Simulator-2) is a flexible tool which enables the performance of various protocols to be investigated in different configurations and topologies. In this environment a network of sensors can be built so that protocols and characteristics are available in the real world (Downard, 2004; NS-2, 2017).
5. **Mannasim** is a module for NS-2 that aims at USN simulation. It provides a sensing model, several application models, several sensor network specific protocols such as LEACH routing protocol, and directed diffusion (Mannasim, 2017).
6. **NRL Sensorsim** is an extension of NS-2 and facilitates sensor network simulation. It provides the opportunity to simulate and detect parameters of carbon monoxide concentration, seismic activity, or audible sound. Wireless sensors, phenomena sources, and gateways can constitute the network (Musznicki and Zwierzykowski, 2012; Sethi et al., 2012; NRL Sensorsim, 2017).
7. **RTNS** (Real Time Network Simulator) software simulates mechanisms of OSs for applications in distributed networks. It combines NS-2 environment and Real Time Operating System SIMulator (RTSim) to simulate CPU in real time (Pagano et al., 2007; Pagano, 2010; RTNS, 2017).

8. **TRAILS** (Toolkit for Realism and Adaptively In Large-scale Simulation) is an extension of NS-2. TRAILS adds functionalities into NS-2 and optimizes its operation. It facilitates the execution of advanced mobility patterns, obstacle presence and disaster scenarios, and failures injection that can dynamically alter over the simulation execution (Chatzigiannakis, 2008).

9. **PiccSIM** (Platform for integrated communications and control design, Simulation, Implementation and Modeling) is a simulation platform for (wireless) networked control systems that uses NS-2 and MATLAB/SIMULINK tools. It aims to deliver a complete toolset for the design, simulation and implementation of wireless control systems (PiccSIM, 2017).

##### • NS-3 and its derivative

10. **NS-3** is a discrete-event network simulator for internet systems targeted primarily for research and educational use. Although the NS-2 simulator is popular, the need for performing core refactoring, integration, software and documentation maintenance, and simulator extension necessitated a new simulator, NS-3. In general, NS-3 is introduced to solve problems present in NS-2. Indeed, NS-3 is not backward compatible with NS-2; it is built to replace NS-2. Specifically, the main contributions that NS-3 can offer comparing with NS-2 are as follows. In NS-2, bi-language system make debugging complex (C++/Tcl), but for NS-3 only knowledge of C++ is enough (single-language architecture is more robust in the long term). NS-3 provides a lower base level of abstraction compared with NS-2, allowing it to align better with how real systems are put together. Some limitations found in NS-2 (such as supporting multiple types of interfaces on nodes correctly) have been remedied in NS-3. NS-3 provides features not available in NS-2, such as an implementation code execution environment (allowing users to run real implementation code in the simulator). NS-3 has better scalability than NS-2. NS-3 has an emulation mode, which allows for the integration with real networks. In contrast, NS-2 is preferred by several users in the community due to the following reasons. Since NS-3 is under development, there is very limited number of models and contributed codes in NS-3 in comparison with NS-2; NS-3 still requires strong community participation to improve it. NS-3 is a new simulator that does not support the NS-2 APIs. Owing to NS-2's long history, it has a more diverse set of contributed modules than does NS-3. However, NS-3 has more detailed models in several popular areas of research (including sophisticated LTE and WiFi models). Picking NS-2 or NS-3 relates to the availability of models and the familiarity of users with the tools; however, the tool that is being actively developed has the priority (i.e., NS-3) (Henderson, 2006; NS-3, 2017).

11. **Symphony** is a simulation framework in association with NS-3, by which the entire processes of actual hardware and software can be

106	TimSim	Shandong University, China	N/A	2013	N/A
107	JSensor	Federal University of Ouro Preto, Brazil	N/A	August 2014	<a href="http://www.joubertlima.com.br/JSensor/">http://www.joubertlima.com.br/JSensor/</a>

modeled. It allows real code adjustment as well as hardware components performance evaluation on applications and protocols in large-scale USN systems (Riliskis and Osipov, 2015; Symphony, 2017).

#### • OMNeT++ and its derivatives

12. **OMNeT++** (Objective Modular Network Testbed in C++) is a component-based and modular simulation which is designed to simulate communication networks and other distributed systems (Mallanda, 2005; OMNeT++, 2017). It attempts to fill the gap between open-source software (e.g., NS-2) and expensive commercial alternatives (e.g., OPNET) (Varga and Hornig, 2008).
13. **SENSIM** (SensorSimulator) is a large-scale sensor network simulator for OMNeT++ to compute energy consumption. It is based on a parallel discrete-event system. It integrates common sensor network protocols, including MAC, network, and application as well as an adapted architecture for future protocols (Cheour, 2013; Mallanda, 2005; SENSIM, 2017).
14. **LSU SensorSimulator** is a customizable framework for USN simulation. It tests and investigates robustness, scaling, networking, and phenomenological issues to find efficient algorithms for distributed sensors (Suri, 2005).
15. **Castalia** is an application- and discrete-level simulator designed on the top of OMNeT++. It is designed to evaluate various platforms because it is highly parametric and can simulate a wide range of platforms (Pediaditakis et al., 2007; Castalia, 2017).
16. **SolarCastalia** or Solar Energy Harvesting Wireless Sensor Network Simulator is a USN simulator based on Castalia which uses solar energy as the energy source. It provides high energy density, high conversion efficiency, and periodicity (Yi et al., 2014).
17. **MiXiM** (mixed simulator) is a cross-level OMNeT++ modeling framework created for mobile and fixed wireless networks. It consists of basic components including, environment, connectivity, reception and collision, protocol library, and experiment. It also supports visualization, monitoring, and debugging in the simulation process (MiXiM, 2017).
18. **NesCT** is a translator from the NesC (Network embedded system C language) programming language to C++ classes for OMNeT++. NesC is an event- and component-driven application simulator. In this way all features of OMNeT++ and Mobile Framework (MF) can be used for simulation (NesCT, 2017).
19. **PAWiS** (Power Aware Wireless Sensors) simulator was developed to facilitate the design and simulation of USN. It is based on the OMNeT++ simulator and the idea of decomposing the node into functional blocks which can be hardware or software (Weber et al., 2007; PAWiS, 2017).

#### • GloMoSim and its derivatives

20. **GloMoSim** (Global Mobile system Simulator) is a library for parallel simulation of large-scale ubiquitous networks in which each library module simulates a particular wireless protocol in the protocol stack (Zeng et al., 1998; GloMoSim, 2017).
21. **QualNet** is a discrete-event simulator and a commercial extension of GloMoSim for scalable network technologies (Siraj et al., 2012). It has been enhanced over during time by the inclusion of satellite, cellular, and new sensor network library (Varshney, 2007). Considering all the QualNet functionalities plus a real-time network emulation interface, EXata is introduced which enables live hardware integration in a seamless manner with the simulated virtual network models, and live applications to run across the virtual environment (QualNet, 2017). sQualNet is a scalable sensor network simulation framework based on QualNet (Vasu, 2005).
22. **SenQ** is a scalable simulation and emulation framework for sensor networks based on QualNet. It is efficient and flexible for different

applications and protocols, and can model battery power and clock drift accurately (Varshney, 2007).

#### • Worldsens and its derivative

23. **Worldsens** is an integrated environment for developing USN applications. It can be used for debugging and performance evaluation because of accurate timing. It consists of two simulators: (1) WSim; and (2) WSNet, which may perform independently or in conjunction during application execution (Fraboulet et al; Worldsens, 2017).
24. **WSNet** is an event-driven and large-scale USN simulator (Dwivedi and Vyas, 2011). It is designed to simulate the environment with a concentration on physical measures and simulates components of the nodes and properties of the radio channel (WSNet, 2017).

#### • Other general-purpose simulators

25. **AlgoSenSim** is an algorithm-oriented framework that is used to simulate network-specific algorithms like localization, distributed routing, and flooding. Its main purpose is to facilitate the implementation and quality analysis of new algorithms (AlgoSenSim, 2017).
26. **NetTopo** is an algorithm level, large-scale network simulator which mainly focuses on USN data structure, logic, and presentation of the algorithms. It was developed in Java and provides both simulation and visualization functions (Shu, 2011; NetTopo, 2017).
27. **SENSE** (Sensor Network Simulator and Emulator) is a component-oriented general-purpose network and application level simulator. It supports an energy model that is compatible with USN. The most important point about SENSE is its balanced consideration of modeling methodology and simulation efficiency (Chen, 2005; SENSE, 2017).
28. **JiST/SWANS** (Java in Simulation Time) is a discrete-event simulation system that embeds simulation time into a virtual machine. It is efficient and transparent within a standard language (Barr et al., 2004). SWANS (Scalable Wireless Ad hoc Network Simulator) is a scalable wireless network simulator built atop the JiST platform. It was designed because existing network simulation tools are insufficient for current research needs, and its performance serves as a validation of the virtual machine-based approach to simulator construction (JiST/SWANS, 2017).
29. **Sinalgo** (Simulator for Network Algorithms) is an algorithm-based simulator that offers a message passing view of the network which captures well the view of the network device. It concentrates on the verification and testing of network algorithms (Sinalgo, 2017).
30. **SimPy** is a process-oriented discrete-event simulator. It may be utilized for asynchronous networking or to implement multi-agent systems (with both simulated and real communication) (SimPy, 2017).
31. **MSPSim** is an extensible simulator for the MSP430 microcontroller at the instruction-level. It is designed to be used in a larger sensor network as a component to support cross-level simulation (Eriksson, 2007; MSPSim, 2017).
32. **COOJA** (CONTiki OS JAva) is a cross-level simulator and simulates at many levels of the system simultaneously. It is interchangeable and extensible to change all the levels of the system, and combines low- and high-level simulation of sensor node hardware and behavior in a single simulation (Osterlind, 2006; COOJA, 2017).
33. **J-Sim** (formerly JavaSim) is component-based software architecture: ACA-the autonomous component architecture-and a compositional network simulation and emulation environment. Components are the basic entities in the ACA which communicate with one another through their ports (Sobeih, 2006; J-Sim, 2017). G-JSIM is a GUI tool for USN simulations under J-Sim platform (Neves et al., 2008).

34. **NetSim** is a network-based environment for modeling and simulating discrete-event applications to simulate Cisco Systems networking hardware and software. NetSim has been widely used for network design validation in sensor deployment (McGrath, 2004; NetSim, 2017). sNetSim can be utilized for analyzing data packet delivery, probability of discarded packet, and other parameters in USN.
35. **OPNET** (Optimum Network Performance) Modeler or Riverbed Modeler was the first commercial network simulator developed in 1987. It is a discrete-event, object-oriented, and general-purpose network simulator. It is well-known because of its capability to provide accurate modeling of the radio transmission (Patil and Hadalgi, 2012; OPNET, 2017). The educational version of it is called OPNET IT Guru (OPNET IT Guru, 2017).
36. **SSFNeT** is a number of Java network models built over the Scalable Simulation Framework (SSF). It is difficult to interact with a simulator because of a command-line user interface; it is therefore only suitable for static applications, but does provide the capability of parallel simulation (SSFNeT, 2017).
37. **NCTUns** (National Chiao Tung University Network Simulator) is an event-driven simulator based on a Linux OS. It enables several simulations of various protocols used in both wired and wireless IP networks. NCTUns provides high simulation speed when traffic load is light and can be turned into an emulator by slowing down and synchronizing the virtual clock with that in real life (Wang et al., 2007; NCTUns, 2017). The NCTUns 6.0 version supports large-scale microscopic wireless vehicular network (WVN) simulation (Wang and Lin, 2010).
38. **SystemC** is a modeling platform including libraries to support design abstractions for modeling hardware, software, and networks with the same language (Fummi, 2007; SystemC, 2017).
39. **Wireshark** (formerly Etherreal) is a network simulator and analyzer capable of USN modeling and evaluation. It is based on the packet analysis as well as applicable for trouble shooting, examining network security, and the development of software and communication protocols. It supports over 750 protocols, which may be exceeded due to its open-source specification (Orebaugh et al., 2006; Wireshark, 2017).
40. **MATLAB SIMULINK** can be used as an USN simulator (MATLAB SIMULINK, 2017). The unique feature of this simulation tool is its capability to determine the effects of different channel parameters such as signal to noise ratio, attenuation, and interference (Ali, 2012; Ali et al., 2010). The authors of a research contribution (Harding et al., 2007) have developed an interface between MATLAB and OPNET to perform much stronger simulation.
41. **LabVIEW** is a development environment suitable for visualizing, creating, and coding engineering systems. It enables USN simulation. By programming sensor nodes, an individual can customize the node behavior to increase acquisition performance, interface directly with sensors, and extend battery life (LabVIEW, 2017).

### 5.1.2. Specific-purpose simulators

#### • Topology control simulators

42. **Atarraya** is a discrete-event simulation tool to test the implementation of topology control protocols in USN. This simulator encompasses structures for designing topology construction and maintenance protocols (Wightman and Labrador, 2009; Atarraya, 2017).
43. **Cell-DEVS** (Cell-Discrete-Event systems Specifications) is a discrete-event simulator that is used to model systems that can be represented as cell spaces. It is an efficient simulation model to implement topology control algorithms for a large-scale USN (Qela et al., 2009; Cell-DEVS, 2017).

#### • Agent-based simulators

44. **ABMQ** (Agent-Based Modeling and Simulation) is a platform based on Qt Application Framework, appropriate for modeling and simulation of self-organization in wireless networks, and particularly Mobile Ad Hoc Networks (MANETs) (Noormohammadpour, 2013).
45. **MASON** (Multi-Agent Simulator Of Neighborhoods/Networks) is a rapid discrete-event multi-agent simulation library written in Java. It is comprised of a model library, and 2D and 3D visualization tools (Zhang, 2012; Luke, 2005; MASON, 2017).
46. **RepastSNS** (Recursive Porous Agent Simulation Toolkit Sensor Network Simulation) is an event-based simulator developed for testing sensor networks from a multi-agent perspective. This platform is an extension of Repast3 (Repast3, 2017) as it has additional features for sensor network simulation (RepastSNS, 2017; Collier, 2001). RepastSNS has two advantages: (1) it provides many abstraction level descriptions, and (2) it is easy to insert USN components for simulation (del Carmen Delgado-Roman et al., 2013).
47. **NetLOGO** is a free platform for multi-agent programming and modeling. It provides the opportunity to simulate USN projects, e.g., energy efficiency (Energy Efficiency Simulation, 2017) and data dissemination flooding technique (Data Dissemination, 2017).
48. **SXCS** (SensomaX Companion Simulator) is a hybrid agent-based multi-operational simulator aimed at the simulation of multiple concurrent applications in USN. It is designed for emulating Sensomax (Haghighi and Cliff, 2013) middleware, which is an agent-based middleware with multiple concurrent application support for dynamic data gathering in large-scale USN (Haghighi, 2013).

#### • Ubiquitous computing simulators

49. **4UbiWise** is a simulator for ubiquitous computing. It focuses on the way that devices compute communications through the physical environment. Ubiwise not only simulates the prototype of devices and protocols in the network, but also simulates the physical environment (Barton and Vijayaraghavan, 2003; UbiWise, 2017).
50. **UbikSim** is a simulator for ubiquitous computing that aims to reduce the features of services experiments and applications for treatment appertain related to both the physical environment and users. It proposes substantial techniques for implementing new sensor configurations, e.g., type of event detection or the required range of coverage (Campuzano, 2011; UbikSim, 2017).
51. **TATUS** is a ubiquitous computing simulator that enables researchers to define and test various scenarios. Meanwhile, a part of software-under-test may be connected to the simulator in order to develop its own representation of the world (O'Neill, 2005).

#### • Underwater simulators

52. **UWSim** is a simulator designed for Underwater USN (UUSN). This simulator considers factors that affect USN underwater and adapts scenarios with this condition, such as providing low bandwidth, low frequency, high transmission power, and limited memory (Dhurandher, 2008; UWSim, 2017).
53. **SUNSET** is an environment for simulation, emulation and also testing (underwater) various communication protocols. Its functionality is at MAC and Routing Protocols based on NS-2 and the extension NS-2-Miracle (Baldo, 2007). By using SUNSET, different acoustic modems and sensing devices can be implemented (Petrioli and Petroccia, 2012; Petrioli et al., 2013; SUNSET, 2017).
54. **SUNRISE** is another UUSN, designed for sensing, monitoring and actuating underwater surroundings. It performs over SUNSET

- platform for designing, implementing, and validating USN protocols (Petrioli, 2014; SUNRISE, 2017).
55. **DESERT** (DEsign, Simulate, Emulate and Realize Testbeds for underwater network protocols) is a complete set of public C/C++ libraries which support the application and transport layers through the network, data link, and physical layers (Masiero, 2012; DESERT, 2017).
  56. **RECORDS** (Remote Control Framework for Underwater Networks) is an open-source environment for underwater networks composed of acoustic nodes. MAC, network, transport, and application layers all are supported by the RECORDS (Toso, 2014; RECORDS, 2017).
  57. **Aqua-Net** is a generic architecture for underwater sensor networks. Aqua-Net enables a powerful networking solution kit which facilitates UUSN study and application development (Peng, 2009; Aqua-Net, 2017).
  58. **SeaLinx** is multi-instance protocol stack architecture for underwater acoustic networking. It is a Linux implementation of Aqua-Net and enables users to exploit their hardware more efficiently by allowing applications to run simultaneously on a modem while also providing better support for cross-layer communication (Le, 2013; SeaLinx, 2017).
  59. **Aqua-Net Mate** is a real-time virtual channel modem simulator for Aqua-Net that supports underwater networks communication (Zhu, 2013).
  60. **Aqua-Lab** is an underwater acoustic sensor network lab testbed for UUSN. It is comprised of hardware, software, program library, an emulator, and real acoustic communication channels (Peng, 2007; Aqua-Lab, 2017).
  61. **Aqua-Sim** is another underwater sensor simulator based on NS-2 which can efficiently simulate the acoustic signal attenuation and packet collisions within water. It is extensible, flexible, and independent of the wireless packages (Xie, 2009; Aqua-Sim, 2017).
  62. **Aqua-Tune** provides a standardized platform for testing and bridging the gap between modeling, simulation, and real world field experience for Underwater Networks (Peng, 2011).
  63. **Aqua-GloMo** is an acoustic-based communication simulator built on GloMoSim simulator. It is designed for network layers protocols and physical layer protocols of UUSN (Dhurandher et al., 2012).
  64. **Aquatools** is a simulation toolkit targeted for simulating underwater acoustic networks with static and mobile nodes. It works in physical layer, MAC layer, routing layer, and energy consumptions schemas (Sehgal et al., 2010).
  65. **UANT** (Underwater Acoustic Networking platform) aims to address the constantly changing underwater acoustic channel with re-configurability. It supports the physical and MAC layer of the ISO Model (Noh et al., 2015; UANT, 2017).
  66. **WOSS** (World Ocean Simulation System) is a simulator based on NS-2 for underwater networks which incorporates a ray tracing tool for a more realistic modeling of underwater propagation (Guerra et al., 2009; WOSS, 2017).
  67. **AUWCN** (Acoustic Underwater Channel and Network) simulator aims to alleviate the inappropriate simplifications and to reproduce most effects existing in the physical acoustic underwater channel (Wolff et al., 2012).
  68. **SAMON** (Ocean Sampling Mobile Network) is a simulator testbed designed to enable simulation of ocean sampling missions involving multiple heterogeneous unmanned underwater vehicles prior to in-water experimentation (Phoha et al., 2001).
  69. **UsNeT** (Underwater Sensor Network Simulation Tool) is developed for underwater communications. It allows real-time process-based simulation and enables three-dimensional deployment (Ovaliadis and Savage, 2013).
- **Other specific-purpose simulators**
70. **Prowler/JProwler** (Probabilistic Wireless Sensor Network Simulator) is an event-driven ubiquitous network simulator which is designed to simulate MICA motes running TinyOS in addition to generic ubiquitous networks. It is used for application testing (deterministic mode), wireless communication channel, and low-level node protocol simulations (probabilistic mode). It supports different plug-ins and any number of sensor nodes in a dynamically changing environment. JProwler is a java-based prowler (Imran et al., 2010; Du, 2010; Kumar and Goyal, 2013; Prowler, 2017).
  71. **Wireless Sensor Network Localization Simulator** is a simple, scalable, and discrete-event simulation system. It engages several mobility models including, Random Waypoint, Modified Random Waypoint, Random Direction, Modified Boundless, Manhattan, Freeway, and RPGM (Wireless Sensor Network Localization Simulator, 2017).
  72. **Sensor Security Simulator (S3)** is a research simulator for evaluating security problems in large-scale sensor networks. It supports the analysis of the impact of selected nodes and encryption keys that compromising the network operation and security (Sensor Security Simulator (S3), 2017).
  73. **Shawn** is a discrete-event customizable simulator for USN. It is designed to simulate hundreds of sensors in network (Kröller, 2005; Shawn, 2017). It simulates only the caused effects rather than simulating the effects of a phenomenon which provides a performance increase (Kellner et al., 2010).
  74. **SIDnet-SWANS** (Simulator and Integrated Development Platform for Sensor Networks Applications) is a simulation-based environment that aims to observe the behavior of algorithm protocols in conditions like phenomena fluctuations or sudden loss of service (Dwivedi and Vyas, 2011). It associates with a graphical representation of the network, and supports defining various phenomenon such as temperature, humidity, and object movements (Ghica, 2010; SIDnet-SWANS, 2017).
  75. **TRMSim-WSN** (Trust and Reputation Models Simulator for Wireless Sensor Networks) is designed to study and compare trust and reputation models over USN and compare the result against other models (Mármol and Pérez, 2009; TRMSim-WSN, 2017).
  76. **WSNimPy** is based on the discrete-event simulator SimPy. It has developed in two versions: (1) WSNimPy (trace), and (2) WSNimPy (synthetic). The first uses trace data from the WSN Profiler, and the second uses a synthetic radio model to simulate communications (Marchiori, 2010).
  77. **SENS** (Sensor, Environment and Network Simulator) is a sensor network simulator for USN applications that is flexible and extensible to change components for applications, network communication, and the physical environment. It supports the development of dependable applications by using diagnostic facilities such as power utilization analysis (Sundresh et al., 2004; SENS, 2017).
  78. **IFAS** (Interactive Flexible Ad hoc Simulator) is a modern and novel approach of ad-hoc simulators. This simulator efficiently accelerates the design and debugging-process of new algorithms by providing unique viewing, debugging, tuning, and interactive capabilities (Ben-Asher, 2007).
  79. **Sidh** is an efficient and large-scale USN simulator in which networks with thousands of nodes in real-time can be supported. It is component-based and flexible in the face of different environmental conditions, sensors, and simulation detail (Carley, 2005).
  80. **SenSor** is an algorithmic simulator that works at a high abstraction level in USN domain. It supports a graphical user interface

- and several extended classes by the user to run simulations (Mount, 2006).
81. **Dingo** is a fork of the SenSor project. Actually, Dingo is a workbench for prototyping algorithms in USN which uses a top-down methodology for design. Since it is not limited to a particular platform, full functionality of a programming language is usable. It has a fixed API, a simple GUI, and base classes which are extensible by the user (Dingo, 2017).
  82. **SNAP** (Sensor Network Asynchronous Processor) is an integrated hardware simulation-and-deployment platform for USN. It lets parallel network simulation with a particular synchronization protocol that is called Time Based Synchronization (TBS). It can be used to build physical as well as simulation nodes (Kelly et al., 2003; SNAP, 2017).
  83. **GTSNetS** is an extension of the Georgia Tech Network Simulator (GTNetS) suitable for USN. It is a large-scale network simulator capable of handling several hundred thousand nodes. It is flexible and capable of implementing diverse protocols, applications, and sensors as well as different energy and accuracy models (Ould-Ahmed-Vall, 2005; GTSNetS, 2017).
  84. **IDEA1** (hierarchical DEsign pLATFORM for sensor networks exploration) is a component-based simulation framework for USN. It is based on SystemC and C++ language. IDEA1 supports transaction-level modeling, and enables easy design space exploration availability (Mieyeville, 2012; Du et al., 2010; IDEA1, 2017).
  85. **WiseNet** is a simulation environment aimed at design, application, and evaluation of secure routing protocols for USN. WiseNet enables the systematic development and investigation of security features of secure and intrusion-tolerant routing protocols (WiseNet, 2017).
  86. **SimGate** is a sensor network simulator which simulates the Intel Stargate device, an element used as a processing, storage, and network gateway unit in sensor network. It is capable of capturing components, including processor, communications, and peripherals (Wen, 2006).
  87. **SimSync** is mainly a time synchronization simulator for sensor networks using a Mica2-a testbed to simulate execution of time synchronization algorithm. The structure of the program in this simulator is table-driven and it can model the clock drift efficiently (Xu, 2006).
  88. **SensorMaker** is a USN simulator for scalable and fine-grained instrumentation. It supports several results such as position, residual energy, energy distribution map, and routing probabilities for each node. It is flexible and provides different kinds of instrumentations (Yi, 2008).
  89. **OLIMPO** is a discrete-event simulation tool designed to ease the design, development, and testing of communication protocols in a sensor network. It provides users with the capability to change various simulation parameters including timers, radio range, and random process (Barbancho).
  90. **DiSenS** (DIstributed SENsor network Simulator) is a scalable distributed simulation system for sensor networks. In addition to emulating many sensors, it includes a distributed memory parallel cluster system and extensible radio models (Wen et al., 2007). S<sup>2</sup>DB is a debugger for sensor networks based on DiSenS (Wen et al., 2006).
  91. **WISDOM** (Wsn mIddleware Service moDules simulatiOn platforM) is designed to simulate the system architecture and components of middleware in USN. It is capable for adding and testing various middleware algorithms (Lim, 2008).
  92. **Sensoria** is a large-scale, user-friendly, and component-based simulator that can efficiently adapt to different levels of details and accuracy in simulation. Its GUI enables users to implement various scenarios and supports different graphical output formats for the results (Al-Karaki and Al-Mashaqbeh, 2007).
  93. **Capricorn** is a large-scale and discrete-event simulator for USN (Sha et al., 2004).
  94. **H-MAS** (Heterogeneous, Mobile, Ad-hoc Sensor network) is mainly designed to provide a convenient platform for evaluating MAS configurations in various network layers. It also provides a user-friendly visualization tool for non-expert users (Mochocki and Madey, 2003).
  95. **SnSim** is an event-driven software tool that is used to balance data quality and USN lifetime in sensor networks. It includes power consumption elements as well as a graphical interface to investigate various aspects of development (Li, 2010).
  96. **SNIPER-WSNim** is a simulator specifically designed for USN. It aims to analyze the nodes behavior in USN as well as studying routing protocols and clustering (Sinha et al., 2009).
  97. **CaVi** is a simulation environment to model a network as a collection of nodes in a sensor network. It provides a uniform interface to simulator Castalia for Monte-Carlo simulation and model checking, as well as tools to evaluate statistical information from simulation (Boulis, 2008).
  98. **WISENES** (WIreless SEnsor NEtwork Simulator) is a packet-level simulator, designed to simulate high-level USN protocols. It also provides accurate information about their performance in a real environment (Kuorilehto et al., 2008).
  99. **WSNGE** is a scalable and user-friendly simulator with an extensible environment for USN. All functions can be run in scripting and visually, and users can view the results in a graphical environment (Karagiannis et al., 2009).
  100. **TikTak** is a scalable simulator for USN. The emulation at the protocol-level increases the simulation speed, and low-level hardware emulation provides the ability to simulate the program and stack latency. It also, allows testing and debugging embedded codes (Menichelli and Olivieri, 2010).
  101. **ShoX** (Scalable ad HOC netwoRK Simulator) is an object-oriented USN simulator. The architecture of the system is an OSI seven-layer model in which all layers are derived from an abstract super class. The most important advantage of this simulator is its comprehensive GUI for configuration, visualization, and statistics demonstration (Lessmann, 2008; ShoX, 2017).
  102. **PASENS** (Parallel Sensor Network Simulator) is an optimal-synchronous parallel discrete-event simulator that was designed to decrease the period of simulation in large-scale USN with large amount of details (Kim and Kim, 2012; PASENS, 2017).
  103. **Glonemo** (GLOBal NEtwork MOdel) is a framework for constructing ad-hoc sensor network models and analyzing them globally at different levels of abstraction. This means it models the hardware including a single node, the protocol layers, the application code, and the abstract model of the physical environment as sensed via sensors (Samper, 2006; Glonemo, 2017).
  104. **Maestro** is a tool for orchestrating simulations in clouds. It enables the entire application to be simulated simultaneously using numerous sensors and actuator devices in an USN and the functionality of the whole system to be evaluated. Maestro can also be incorporated in parallel multiple serial simulations (Riliskis and Osipov, 2014).
  105. **CupCarbon** is a multi-agent and discrete USN design and simulation platform. The sensors can be deployed in Open Street Maps (OSM) and evaluate the behavior of the network and its cost (Mehdi, 2014; CupCarbon, 2017).
  106. **TimSim** is a time-step-based wireless ad-hoc network simulator. It directly simulates the source code of wireless ad-hoc network application and is able to represent the transmitted data at the bit level (Yan, 2013).
  107. **JSensor** provides parallel simulation for USN and distributed systems. It enables synchronous and asynchronous simulation of large sensor networks. The kernel of JSensor is based on Sinalgo. The multi-core architecture allows hundreds of nodes to be simulated simultaneously (Ribeiro, 2012; JSensor, 2017).

## 5.2. USN emulation environments

This sub-section introduces 23 emulation tools and their derivatives. For each tool, the corresponding designer/developer, the latest version, and the software link (if any) are provided in Table 7.

### • TOSSIM and its derivatives

1. **TOSSIM** is an efficient and scalable simulator for TinyOS USN. It has a simple operation environment by using a probabilistic bit error model, and supports various network interactions which make it expensive. It can also be used to discover bugs from network bit-level MAC interactions to queue overflows in ad-hoc routing protocol (Levis, 2003; TinyOS, 2017). The GUI of TOSSIM is known as JTOSSIM. Also, mTOSSIM is a simulator that estimates the battery lifetime in USN (Mora-Merchan, 2013).
2. **PowerTOSSIM z** is a plug-in which models power consumption for TOSSIM. The PowerTOSSIM (PowerTOSSIM, 2017) plug-in for power consumption has not been fully imported to new versions of TOSSIM, so PowerTOSSIM z is developed to simulate MICAz motes. It offers a non-linear energy model to capture the behavior of modern batteries (Perla, 2008; PowerTOSSIM z, 2017).
3. **TOSSF** (TinyOS Scalable Simulation Framework) can create application types on the fly for use in the initialization of the model. It also provides the TinyOS programmer with a set of scripts which adapt the source code to run in the simulator. TOSSF was designed to enhance TOSSIM scalability (Perrone and Nicol, 2002).
4. **TYTHON** is an extension to TinyOS's TOSSIM simulator scripted in

Python. Given its valuable library of scripting, TYTHON empowers users to develop dynamic and reproducible simulation scenarios (Demmer, 2005; TYTHON, 2017).

5. **Mule** is a hybrid simulator based on TOSSIM. It is mainly designed to test and debug USN through a combination of debugging multiple simulated motes on a host with message transmission and sensor data acquisition of physical motes (Watson and Nesterenko, 2004).

### • Avrora and its derivative

6. **Avrora** is a scalable cycle-accurate sensor network simulator with precise timing. It is an instruction-level sensor network simulator which supports more than 10,000 nodes quickly and can handle 25 nodes in real-time (Titizer et al., 2005; Avrora, 2017). **AvroraZ** (2017) is an extension to Avrora for improving MicaZ support and thereby provides IEEE 802.15.4 compliant emulations.
7. **AEON** (Accurate Prediction of Power Consumption) is an extension of Avrora that is utilized to quantitatively predict the energy consumption and estimation of sensor networks (Landsiedel et al., 2005).

### • Other emulators

8. **ATEMU** is a fine-grained sensor network simulator aimed at bridging the gap between actual sensor network deployments and sensor network simulations. The main advantage of ATEMU is its ability to simulate a heterogeneous sensor network (Blazakis, 2004; ATEMU, 2017).

9. **EmPro** is an Environment/Energy Emulation and Profiling Platform for USN. It is designed to emulate environmental conditions, and all inputs to a sensor system including power sources, radio activities, and inputs from external sources. In profiling mode, it can capture the behavior of USN (Park and Chou, 2006).
10. **OCTAVEX** ubiquitous sensor framework is intended to assist a wide range of end users, including systems integrators, software developers, and original equipment manufacturers in developing and handling USN. This framework is a backbone that provides user with the ability to implement an inexpensive end-to-end solution quickly and easily (Dwivedi and Vyas, 2011; OCTAVEX, 2017).
11. **SenseEH** is software framework that enables developers to manipulate the power and speed of a simulation and the reality and accuracy of experiments. It relies on COOJA for emulating the actual code (Dall'Ora, 2014).
12. **HarvWSNet** is considered a suitable tool for the simulation of the network protocols and the lifetime of energy harvesting (EH) of USN. HarvWSNet is based on WSNet and MATLAB. Users may build multi-node network scenarios while imposing a concise description for node energy harvesting, management subsystem, and its time-varying environmental parameters (Didioui, 2013).
13. **UbiSec & Sens** is an architecture for medium and large-scale USN. It contains a comprehensive toolbox of security aware ingredients for sensor network application progression (UbiSec & Sens, 2017).
14. **Emuli** (Emulated Stimuli) is a method of effectively substituting synthetic data for sensor data on physical wireless nodes. It stores the model parameters rather than recording and playing back spot measurements that cause a compact data memory footprint (Clouser et al., 2007).
15. **MEADOWS** is a software framework for Modeling, Emulation, and Analysis of Data Of Wireless Sensor networks. The framework is capable of answering questions about sensor query processing (Luo, 2004).
16. **Freemote Emulator** is a lightweight and visual emulator for USN. It provides a lightweight emulation tool to combine motes and predefined code templates, as well as a layered architecture to produce quick running codes for nodes (Maret, 2008; Freemote Emulator, 2017).
17. **VMNet** (Virtual Mote Network) is a sensor network simulator designed to realistically emulate USN at the CPU clock cycle level. It reports the performance of application in response time, as well as power consumption and emulates peripherals in detail (Wu, 2007; VMNeT, 2017).
18. **WSim** is a sensor node platform emulator which is designed to run, analyze, and debug applications for sensor networks (Musznicki and Zwierzykowski, 2012). It provides hardware platform simulation by microcontroller binary codes and simulates its behavior, as well as any event that occur in the platform (Fraboulet et al; WSim, 2017).
19. **EmStar** is software for developing and deploying USN on Linux. It includes libraries to implement message-passing IPC primitives to deploy, simulate, emulate, and visualize live systems. Further, it contains services to support sensing, networking, and time synchronization (Girod, 2007; EmStar, 2017).
20. **WiEmu** is an open-source agent-based simulator and emulator for heterogeneous USN. Using WiEmu enables the evaluation of the network architecture, topology, and protocols, even when they running on real testbeds (Youssef et al., 2012; WiEmu, 2017).
21. **WiSeREmulator** is an emulation framework for structural health monitoring. It is comprised of two main components: a testbed of wireless sensor nodes, and a software emulation environment (Khandu, 2010).
22. **SUNSHINE** is a scalable hardware-software emulator for sensor network applications. It provides data exchanges and time syn-

chronizations across different simulation domains and simulation accuracy levels (Zhang, 2011; SUNSHINE, 2017).

23. **CORE** (Common Open Research Emulator) is composed of Python modules and GUI for building emulated USN networks. These networks may be connected to live networks (CORE, 2017).

## 6. USN simulator and emulator features

This section outlines the features of the most prominent USN simulation and emulation environments and frameworks. In this context, 22 of the above 130 tools are selected to be compared in detail: those which have been supported by their developers, are popular, have published results, are usable, and have interesting characteristics and features. In this regard, Table 8 presents the features of the selected simulators and emulators, i.e., version type, license type, language/scripting used, open source capability, supported platform, and presence of on-line document or tutorial. Normally, the software is developed for academic, research, and commercial purposes. Academic and research versions of software are free of charge. For commercials, the licenses or affiliated packages are not provided for free for users (the underlined letter demonstrates the extensive use of the software in that version). There are two types of licenses: Gnu's Not UNIX General Public License (GNU GPL) which allows end users to use, study, share, and modify the software freely, and Berkeley Software Distribution (BSD) license, which imposes minimal restrictions on the redistribution of software. A variety of languages and scripts is employed by which the simulators/emulators are designed with, i.e., Java, C, C++, and NesC (Network embedded system C language), where each one has its own pros and cons. Open source software has the benefits of modifiable source code and free extension of the software. But, open source software may not be user-friendly and convenient with GUI. The platforms that simulators/emulators run on vary from Microsoft Windows to Linux and Mac OS. On-line documents, manuals and tutorials may help users to install, get started with, and overcome any difficulties while using the software.

In addition, for each of the selected simulators and emulators, Table 9 shows whether they are general or specific purpose simulator/emulators, support GUI, are object-oriented or component-based, support the level of abstraction, including the energy consumption models, and if any derivative or extension is developed. Simulators and emulators are either general (adaptive) or specific (new) environments. Some of the simulators and emulators are GUI-driven where the user can drag and drop the network components, while others require command line and scripting. Object-oriented based simulators and emulators focus on the relationships between classes and facilitate implementation and extensibility, but they lack scalability. On the other hand, component-based simulators and emulators focus on interchangeable code modules that function independently; thus, they are more extensible and scalable, but may be more difficult to implement in a modularized way (Singh et al., 2008). The simulation abstraction level is described in Section 2.1.4. Alphabetical letters are used to briefly address each simulator and emulator abstraction category: generic network simulator, code level simulator, firmware level simulator, algorithm level simulator, packet level simulator, and instruction level simulator. Energy consumption models consider whether sensor nodes have batteries or produce energy for efficient system design. Simulators and emulators derivatives or extensions are developed to improve the simulators/emulators performance and/or overcome any deficiency.

Qualitative information facilitates the comparison of the simulator/emulator and the process of choosing an appropriate one among several tools. Such classification has more adherents among students since it enables them to compare and assess the tools relatively. In this context, Table 10 gives qualitative details of the selected USN simulation and emulation tools for academic, research, and commercial versions. The first criterion, visualization, is related to the environment where the user is

**Table 8**

Specifications of USN simulators and emulators.

Simulator/Emulator	Version type	License type	Language/scripting	Open source	Platform	On-line document/tutorial
<b>Prowler</b>	r	Free	m-file	No	Linux, Windows, Mac OS	Yes

manipulating his/her practices. Visualization ranges from poor to excellent qualities. Flexibility deals with how many frequent runs and configuration changes may be applied to a simulator/emulator. Scalability, as explained before, represents the number of nodes which a simulator/emulator may handle. Existing protocols in simulators/emulators databases are shown by protocol availability criterion. Radio signals propagate via an antenna from a sensor node. The strength of signals is directly related to the distance. Therefore, the formidable presence of such

modules in USN simulators/emulators is an advantage. The degree of simplicity represents how quickly individuals get familiar with tools, while interactivity demonstrates how easily individuals interact and exploit tools. Such criteria are considerable for academic and educational purposes where increased simplicity and interactivity makes the tool desirable and pleasant (ZVKOVIC, 2014).

A simulator or emulator is designed or developed to fulfill the needs of a project or application. Therefore, we cannot generically and lucidly

**Table 10**

<b>EmStar</b>	Good (r)	Medium (r)	Low (r)	Medium (r)	Average (r)	N/A

name a simulator/emulator as the perfect and flawless tool. What is desirable is to identify the positive and negative aspect of each and pick the one which best fits the application. In this regard, Table 11 summarizes several key features and the limitations corresponding to each simulation and emulation tool.

## 7. Performance assessment of simulators and emulators

Selecting the most appropriate simulator or emulator for USN purpose among the numerous versions available remains a controversial task. Several studies have evaluated the performance of USN simulators and emulators and analyzed and compared the results with each other in terms of popularity, architecture, OS, credibility, accuracy, scalability, execution speed and time, CPU usage, visualization and GUI, debugging, and even learning difficulty criteria. Each study has defined a scenario comprised of several parameters. In this context, Table 12 addresses these efforts in brief.

One approach for conducting a relative comparison of USN simulation/emulation performance is to define scenario(s). Each scenario is comprised of a set of parameters to run. These parameters may vary with respect to simulators/emulators throughput and defined application; however, such tool assessment has some general parameters in common. We categorize these parameters into four groups of node, execution, terrain, and other, as presented in Fig. 7. The node category comprises several qualitative and quantitative features, which are attributed to the sensor nodes, ranging from sensor numbers to sensor functionalities. The execution category is dedicated to all the settings for carrying out a simulation/emulation, such as simulation time, packet characteristic, protocol type, etc. The terrain (field) category is one of the most important components in simulation/emulation. In real-world applications the sensed data from the sensors need to be routed to the targeted sensors/services. Any physical intruder (e.g., wall, topography) that cause problem in proper transmission of these data needs to be simulated in advance. Finally, there are several general and specific components that do not fall into the earlier categories, which are placed in other category.

Although Table 3 has proposed several features for simulation assessment, the most critical one, i.e., scalability (or number of nodes), needs to be assessed specifically for USN simulators and emulators. This feature demonstrates the ultimate throughput of a simulator/emulator in handling a number of sensor nodes effectively. Scalability

is so imperative that the majority of comparative studies in Table 12 have compared it against other performance assessment features (see Fig. 8). A review of the literature acknowledges that the number of sensor nodes directly affects other features, as well as the final performance of the simulator/emulator.

Scalability and the potential number of sensor nodes deployed in simulation and emulation environments have been challenging tasks. Given the widespread and pervasive projects of USN and emerging technologies in USN, simulation and emulation by more sensor nodes can be an advantage. However, a review of the literature ascertains that higher scalability and more sensor nodes heavily increase the execution time, CPU utilization, and memory usage, which affect the delivery success ratio of messages and in some cases delay the message. Fig. 9 demonstrates the approximate number of sensor nodes that a simulator and emulator can handle effectively.

Simulators' and emulators' designers and developers have employed a variety of programming languages for generating such tools. In this research, the programming languages of 102 out of 130 simulators and emulators were found in their corresponding websites and tutorials as well as the articles that firstly introduced the tools. A review of literature demonstrates that almost half of the simulators and emulators are scripted by C/C++ and their derivatives (e.g., C++ Builder, CompC++, NesC, PARSEC), while 39% have made use of Java programming language. In this regard, C/C++ engines are expected to have better functionality and productivity than their Java counterparts. Python is used for developing 6% of simulators and emulators. A small proportion of simulators or emulators have utilized other programming languages (e.g., C# and m-file). This information is illustrated as a chart in Fig. 10.

## 8. Lesson learned, open issues, and future directions

In this section, we first summarize the lesson learned from literature, and then point out some general and specific research directions for USN simulators and emulators.

### 8.1. Lesson learned

This survey has presented several lessons. We have highlighted some tips for students and researchers, for whom this paper has been targeted at. The study should clarify the choice of a simulator or an

**Table 11**

Key features versus limitations of USN simulators and emulators.

Simulator/ Emulator	Key Features	Limitations
<b>Prowler</b>	<ul style="list-style-type: none"> <li>Rich library of radio modules and protocols</li> <li>Extendable for general platforms</li> <li>Easy prototyping of applications</li> <li>Integration of different optimization algorithms</li> <li>Provide GUI and good visualization capabilities</li> <li>Good extensibility via plug-ins</li> </ul>	<ul style="list-style-type: none"> <li>Provides only one TinyOS MAC protocol by default</li> <li>No sensor node energy modeling</li> <li>No 3D space simulations</li> <li>No detailed antenna modeling in the package</li> </ul>

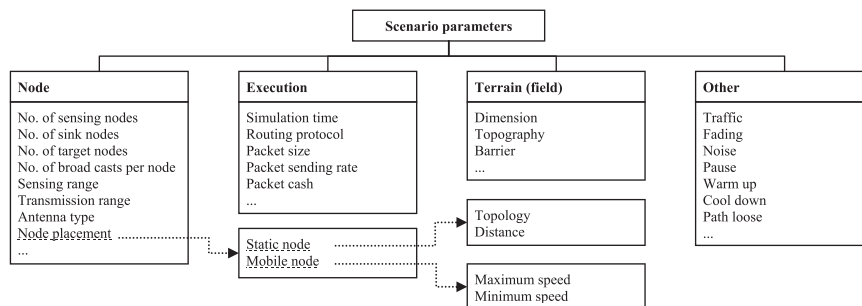

Fig. 7. Scenario parameters for USN simulation and emulation.

Fig. 8. Pairwise performance assessment: number of nodes feature versus other simulator's/emulator's features.

emulator. The goal of design and development of a simulator/emulator varies among the available versions. Each tool has its own advantages and disadvantages. So, choose the one that best fits your application, effort, time, and budget. Most of the presented USN simulators and emulators fall into research and commercial domains. Among the simulators, NS-2, OPNET, and QualNet, and for the emulators, TOSSIM, have gained more popularity. From an educational perspective, limited tools are available that have an academic version released. Among them, OPNET IT Guru and OMNet++ have gained more attention, especially due to their free license, rich tutorial, and excellent GUI. A good GUI facilitates interaction between users and software by dragging and dropping the simulation elements and presenting the outputs graphically. However, if a student neglects the GUI and can get

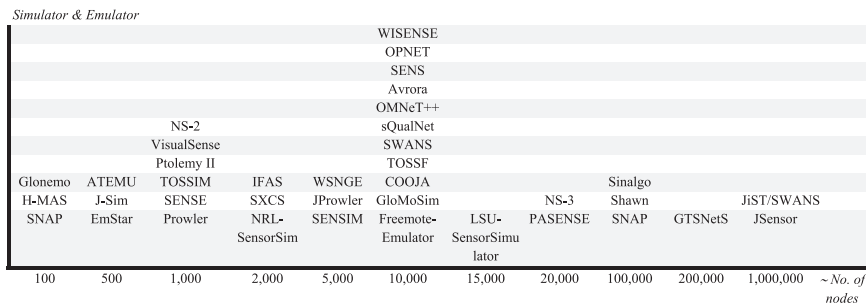

Fig. 9. Simulators' and emulators' scalabilities: approximate number of supported sensor nodes.

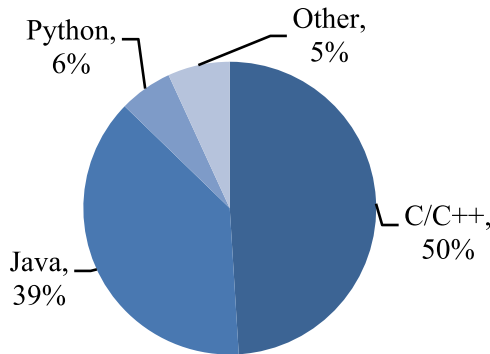

Fig. 10. Percentage of simulator/emulator programming languages.

familiar with scripting, NS-2 and NS-3 are suitable educational tools. Last but not least, an open source facility enables modification of current programs and free extension of the software. However, they may not be user-friendly and convenient with GUI. NS-2 and OMNeT++ are two frequently used open source software.

Choosing an authoritative tool that provides flexible modeling and validation can drastically improve the results. Also, the tool should enable statistical analysis of output data. Users/developers should ensure the validity of the model inputs and outputs. Researchers and tool developers should consider the positive and negative aspects of simulators/emulators, appropriate programming language, architecture (i.e., component-based or object-oriented architecture), degree of simulator/emulator complexity, presence and shortage of features, parallel execution, real deployment of sensor nodes, and several other factors.

Researchers normally execute simulation/emulation repeatedly by using one simulator/emulator. It should be noted that execution of several runs does not necessarily results in better results. The simulation/emulation outputs are directly related to the mathematical models developed in that specific tool. The variation in the built models leads to discrepancies among the simulation/emulation outputs. Although simulation/emulation models should be built credibly, more complex models require more computational time and resource. A good USN simulator/emulator, however, offers a balance between several criteria, such as accuracy, scalability, feature, extendibility, scripting language, GUI support, and ease of use.

## 8.2. Future work

Many types of research have been conducted addressing simulation and emulation issues in USN. However, there are still a lot of potential future studies which either remain unsettled or unexplored comprehensively. We classify them into general and specific open issues. From the general perspective we have identified the following trends.

- A promising future work relates to deeply reviewing other performance evaluation techniques (i.e., analytical modeling, physical

testbed, and real world experimentation) suitable for USNs along with addressing a standardized criteria list for assessing the performance of such techniques.

- Interoperability of USN simulators/emulators is a topic that has not been deeply explored so far; that is, developing integrated simulators/emulators to support a wide range of features. In this context, one tool can be complemented by other tools for their distinctive features such that the output of one can be imported as an input to the other one. To this end, a model can be analyzed through different simulation tools synchronously/asynchronously. This enables the strengths and weaknesses of the model to be revealed and makes the model possible to be improved in the design process. Experimenting with multiple simulators/emulators is a non-trivial challenge and should be supported with a common API for all participants.
- USN has gained attention in different indoor and outdoor applications, such as health, transportation, agriculture, and military, to name a few (Keshteh Gar and Sadeghi-Niaraki, 2015; Sahelgozin et al., 2015; Nikparvar et al., 2014; Jamali and Sadeghi-Niaraki, 2016; Moosavi and Sadeghi-Niaraki, 2015). These applications have specific characteristics that are coupled with technology. Therefore, there is an enormous potential to run and test application-specific scenarios through USN simulators and emulators. Since simulations and emulations can reveal design flaws to a large extent, the scenarios need to compare different parameters to increase the knowledge about impacting factors.
- Given the ability of simulators/emulators in modeling sensor networks in diverse scales, exploring their capabilities in terms of terrestrial, underground, underwater, multi-media, and mobile USNs is an interesting area of research that can be carried out in future.

Besides the aforementioned general directions, we also highlight the following specific issues, which are not fully addressed or remain unaddressed by the current USN simulators and emulators so far. A promising future direction can be toward extending the functionality of simulators and emulators, especially the open-source ones, which suffer from the appropriate extension/feature of the USN emerging technologies (e.g., cognitive radio sensor networks, the Internet of Things (IoT), cloud computing, etc. (Islam et al., 2016)).

- **Cognitive radio sensor networks:** In applications that require a large number of sensor nodes, the available bandwidth may not suffice to support all the transmissions, which can result in loss of useful data. In order to minimize data loss, an emerging trend in USNs is to equip the wireless sensor nodes with cognitive radio (CR) technology. CR is an adaptive, intelligent radio and network technology, capable of automatically detecting vacant channels (termed spectrum sensing) in a wireless spectrum, change their transmission parameters accordingly (termed spectrum decision), and making use of these available channels in an opportunistic manner, improving the overall spectrum utilization (Akan et al.,

2009). Incorporating cognitive radio capability in sensor networks yields a new sensor networking paradigm, termed cognitive radio sensor networks (CRSNs). Depending on the application, a USN composed of sensor nodes equipped with cognitive radio may benefit from its potential advantages. Several researches have investigated the theories behind this technology, such as radio resource allocation in CRSNs (Ahmad, 2015), channel bonding in CRSNs (Bukhari et al., 2016a), and adaptive medium access control in CRSNs (Shah and Akan, 2015), to name a few. In spite of these considerations, the majority of researchers are using analytical methods to understand the behavior of CRSNs and a very few simulation models at present are providing support for combined features of USNs and CRSNs. Accordingly, CRSNs has not been a main research focus in USN simulators and emulators. As an exceptional and pioneering study, a NS-2 based CRSN simulator model was proposed by (Bukhari et al., 2016b). This model supports the fundamental requirements of a CR-based wireless sensor network. As the research trend is shifting towards CRSNs technology, there is a possibility of examining different aspects of such technology and practically identifying the challenges in multiple applications (e.g., indoor sensing, multimedia, multiclass heterogenous sensing, real-time surveillance, etc.) by USN simulators and emulators for future research.

- **Energy management and harvesting:** In USN applications static and dynamic sensor nodes are normally dispersed over a large area while they are prone to failure due to energy depletion. Exploiting power suppliers from fixed utilities may not be technically or economically possible in all practices. Therefore, energy management, harvesting, and replenishment become crucial to maximizing sensor networks' lifetimes and throughputs (Niyato et al., 2007; Akhtar and Rehmani, 2015). Despite the plethora of theories relevant to these issues, very few researches have pointed out the difficulties in energy efficient protocol design using simulators/emulators; for example, Hasenfratz (2010) analyzed and compared a limited number of routing protocols for energy harvesting USNs in different scenarios by the Castalia simulator. Therefore, measuring the energy consumption of the (mobile) sensor nodes and experiencing energy efficient protocols are topics that have not been deeply explored in simulators/emulators thus far. More specifically, energy saving mechanisms (e.g., energy-efficient routing protocol, power-conserving MAC protocol, battery management, energy-efficient packet scheduling, etc. (Niyato, 2007)) besides renewable energy resources (e.g., light, vibration, heat, radio frequency, wind, etc. (Akhtar and Rehmani, 2015)) are the issues that can be individually or collaboratively investigated by different applications in USN simulators and emulators.
- **The Internet of Things:** During recent years, a lot of attention has been towards establishing infrastructures for smart and context-aware environments (Sharif and Alesheikh, 2017). In this respect, in the Internet of Things (IoT) paradigm, concurrent collection of data from numerous devices and communications between them has been a challenging task for network technologies. To overcome this challenge, sensor networks try to complement the sensing and communication infrastructures. The integration of sensor networks and IoT is theoretically discussed in Alcaraz (2010). Also, the review by Rashid and Rehmani (2016) demonstrates the utility of IoT and USN integration in real-world applications. Therefore, in the light of USN simulators and emulators, exploring the scalability and topology issues along with communication protocols, targeting at IoT applications, can be an interesting topic for prospective research.
- **Cloud computing:** For ubiquitous applications, the collected data by sensor nodes need to be available at any time, at any place. However, due to the limitations of sensors in storage, bandwidth, battery power, processing, security, etc., one drastic solution for communication among sensor nodes is using cloud infrastructure. High-performance computing, less maintenance, seamless availabil-

ity, and scalability are only a few features of cloud computing. Therefore, combination of USNs with clouds enables sharing and analyzing real time sensor data pervasively on-the-fly. A USN-Cloud platform normally comprises of USN, cloud infrastructure, and client(s). USN consists of physical wireless sensor nodes to sense the environment and route the data to the cloud. The cloud provides the client(s) on-demand data/service over the Internet. Despite the effectiveness of USN-Cloud computation, very few works have undertaken specific features of it. Kurschl and Beer (2009) presented a model by combining the concept of USNs with the cloud computing paradigm, and demonstrated that how both can benefit from this combination. Ahmed and Gregory (2011) proposed a novel framework to integrate the cloud computing paradigm with USN, aiming to facilitate the shift of data from USN to the cloud environment. In this perspective, more general models must be further developed and be evaluated in different scenarios to measure the advantages and shortcomings of USN-Cloud combination. A large part of the work can be handled in USN simulators and emulators through developing patches/extensions. Then, the output of simulators/emulators can be imported as input for cloud computing.

## 9. Conclusion

The purpose of this study was to expand the understanding of researchers and tool developers about the available simulation and emulation tools for USN. We believe this study will aid them in choosing an appropriate simulator and/or emulator for sensor network performance testing based on their requirements and constraints. In this context, this paper overviewed 130 simulator and emulator environments and frameworks that were originally designed or adapted for USN. The brief explanation provided for each tool accompanied by corresponding designer/developer, the latest version, and the software link. A number of prominent USN simulators and emulators were qualitatively and quantitatively compared based on multifarious criteria: those that are available for the community and supported by their developers, are popular, have published results, and have interesting characteristics and features. The strengths and weaknesses of each were comparatively addressed as well. Several studies that cited relative performance analysis of simulators and emulators were introduced. Finally, we summarized with some recommendations for potential future works. We conclude from the observations that choosing an appropriate simulator/emulator and building a correct simulation model are two important aspects for USN. However, there is no standard simulator or emulator for all USN applications; its choice depends on the operational environment.
